

Bayesian Inference for Phenotypic and Palaeo Data

- Bayesian phylogenetics (especially BEAST) has a lot to offer for morphologists and palaeontologists
- Peculiarities of morphological / palaeontological data
- Some case studies
 - Cambrian trilobites (evolutionary rates)
 - Crocodile evolution (detecting convergent evolution)
 - Lizard viviparity (ancestral state reconstruction / overparameterisation)

Bayesian Inference for Phenotypic and Palaeo Data

- Bayesian phylogenetics (especially BEAST) has a lot to offer for morphologists and palaeontologists

- Some case studies
 - Cambrian trilobites (evolutionary rates)
 - Crocodile evolution (detecting convergent evolution)
 - Lizard viviparity (ancestral state reconstruction)

Trilobites and the Cambrian explosion

The Cambrian Explosion

Cambrian Explosion

Late Precambrian ~560mya

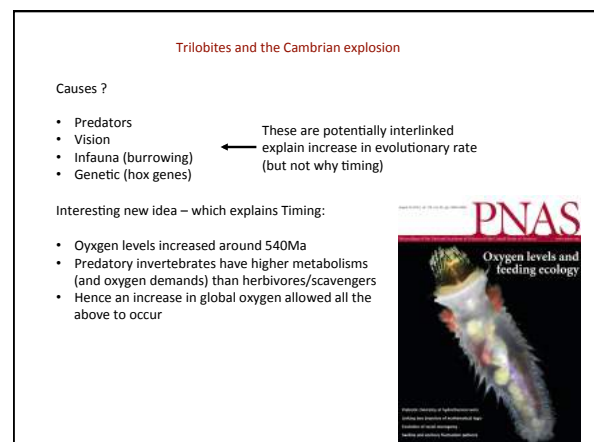

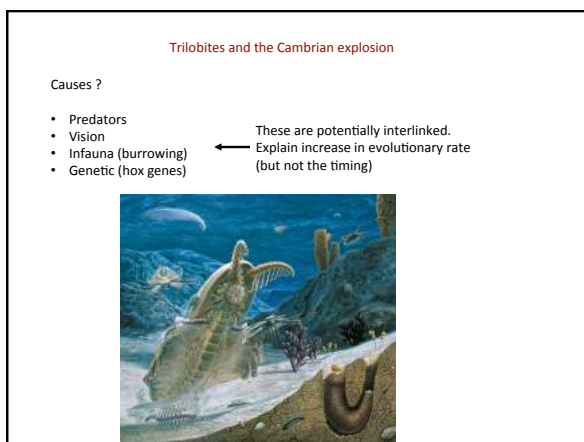

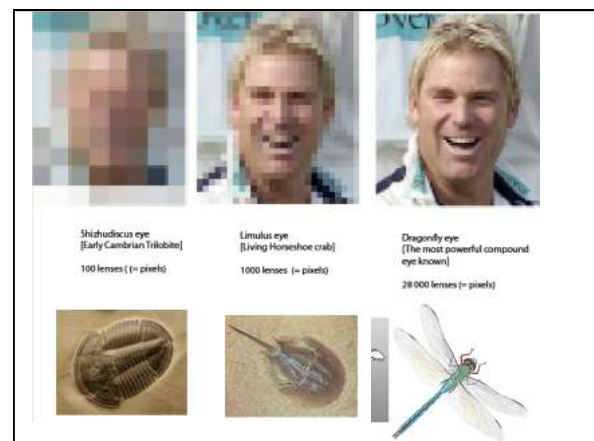

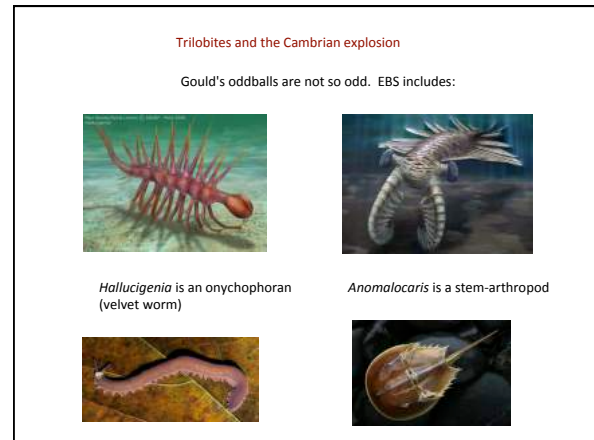

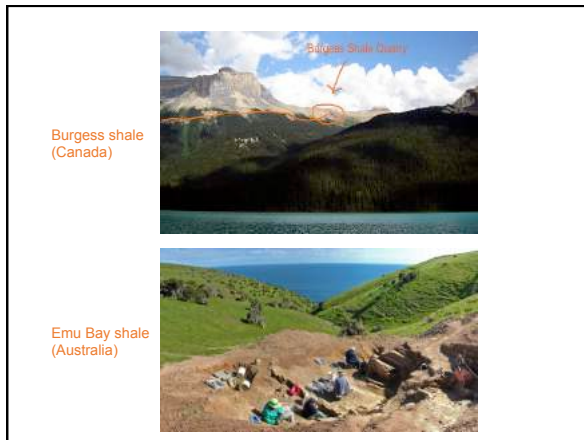

Low diversity
Simple organisms, no complex senses
No predation (simple food webs)
2d ecosystems: No nekton (active swimmers)
No infauna (burrowers)

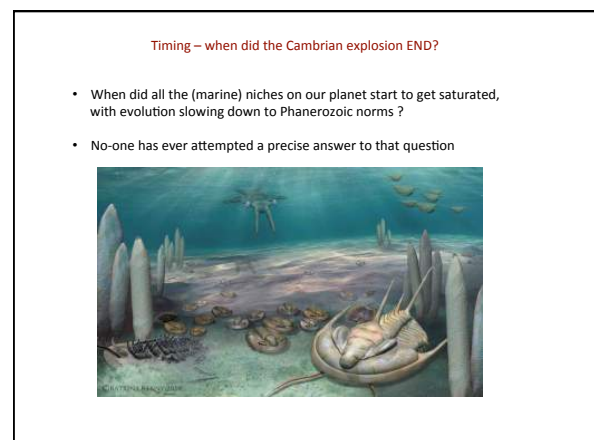

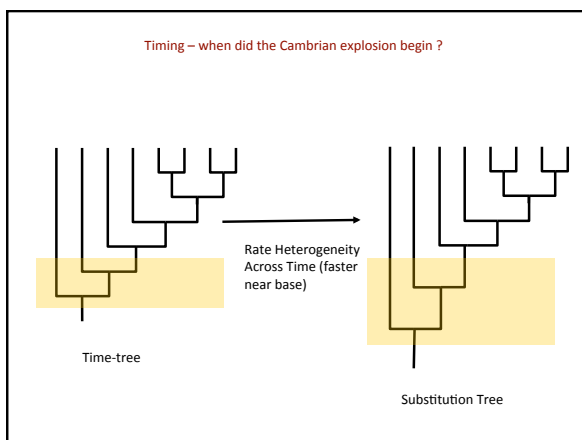

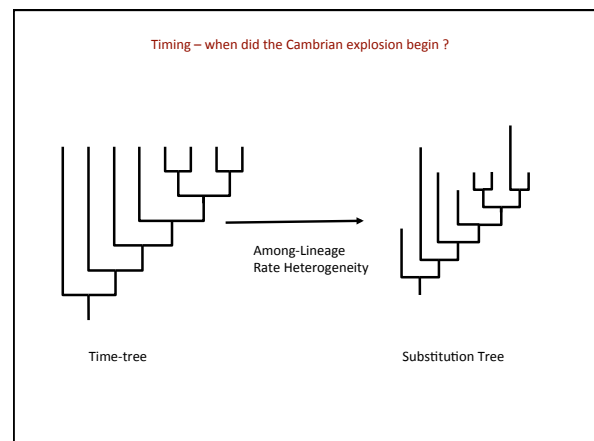

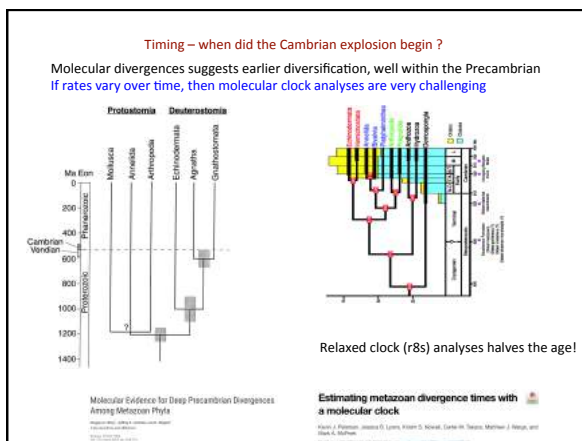

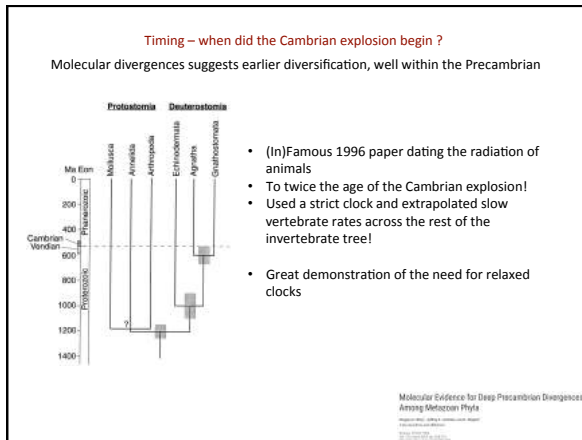

Cambrian onwards ~540 mya

High diversity (nearly all fossilizable phyla)
Complex organisms (eyes, appendages etc)
Predator-prey interactions (complex food webs)
3D ecosystems: Nekton (active swimmers)
Infauna (burrowers)

Burgess shale (Canada)

Trilobites – the best group for Cambrian macroevolutionary analyses

- Extremely abundant & diverse (~12% of species in the EBS); the beetles of the Cambrian
- Lots of hard body parts = lots of characters
- They appear as soon as the Cambrian fossil record starts to get good.

Trilobite evolutionary rates constrain the duration of the Cambrian explosion
Mark P. Hickey^{1,2}, Gregory D. Edgecombe^{1,2} and Michael J. Benton^{1,2}

Trilobites – the best group for Cambrian macroevolutionary analyses

- Taxon sampling: >100 species from across most of the Cambrian
- Character sampling:
 - discrete traits
 - continuous traits
 - meristic traits

Trilobites – the best group for Cambrian macroevolutionary analyses

- Taxon sampling: >100 species from across most of the Cambrian
- Character sampling:
 - discrete traits
 - continuous traits
 - meristic traits
- Tip-dated analyses of combined data
 - BEAST and BEAST2
 - Outbreak Tools

OutbreakTools

Summary
OutbreakTools is the R package created during "The host" a workshop for the analysis of disease outbreaks (2017), which took place at the MRC Centre for Outbreak Analysis and Modelling at Imperial College, London, in January 2017. The purpose of OutbreakTools is to support the development of tools for storing, handling and visualising disease outbreak data, as well as simple analysis tools.

Features
OutbreakTools offers a range of tools for storing, handling and visualising disease outbreak data (e.g. tips, dates, any type of observational data) made on the subjects (e.g. symptoms, events, DNA, sequence collections), i.e. tips or dynamic outbreak between subjects, or outbreak information (e.g. whether infections, or other interventions), i.e. and then of phylogenetic trees, various types of graphs, visualisation of samples per individual, geographic distribution of the samples, contact networks, phylogenetic trees, network clustering trees (e.g. development, separation of evidence, based on any time-scaled information).

Epoch 3
Late Cambrian)

Epoch 2
(Mid Cambrian)

Epoch 1
(Early Cambrian)

Trilobites – the best group for Cambrian macroevolutionary analyses

Conclusions

- The Cambrian explosion was already over by the time the first trilobites appear 520 M
- By the time the 'typical' Cambrian fossil record commences, it was evolutionary 'business as usual'
- The Cambrian explosion was briefer, and ended more abruptly, than previously believed
- The Burgess Shale, EBS and other famous Cambrian fossil sites are not windows into the greatest adaptive radiation of all time (*contra* Gould et al).

Bayesian Inference for Phenotypic and Palaeo Data

- Bayesian phylogenetics (especially BEAST) has a lot to offer for morphologists and palaeontologists
- Peculiarities of morphological / palaeontological data
- Some case studies
 - Cambrian trilobites (evolutionary rates)
 - Crocodile evolution (detecting convergent evolution)
 - Lizard viviparity (ancestral state reconstruction)

Crocodile Evolution

Crocodylians: Diversity and Anatomy

Diversity: ~24 living species

- ~14 species of crocodiles (lower canines exposed)

- ~8 species of alligators including caimans (lower canines hidden)

- 2 species of gavials/gharials (extremely narrow snouts for fish-eating)

Crocodylians: Diversity and Anatomy

Diversity:

- All living crocs are sluggish, amphibious predators
- But fossil crocs were much more diverse
 - Active terrestrial forms (cursorial)
 - Small tree-climbing forms (arboreal)
 - Ocean-going forms

Darren Naish
Tetrapod Zoology

Crocodylians: Diversity and Anatomy

Diversity:

- All living crocs are sluggish, amphibious predators
- But fossil crocs were much more diverse
 - Active terrestrial forms (cursorial)
 - Small tree-climbing forms (arboreal)
 - Ocean-going forms

Crocodylians were probably much more active in the past, and living forms are secondarily sluggish.

- Living crocs still retain many active, bird-like adaptations (fully-divided hearts and unidirectional lungs).

Unidirectional Airflow in the Lungs of Alligators

Gavials

Genomic tree:
Long-snouted forms
are a recent clade

Crocodylians: Long-snouted forms

Most fossils fit the genomic scheme.... Except for thoracosaur

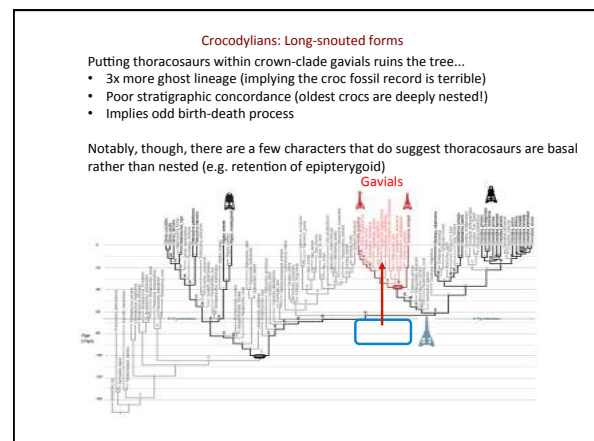

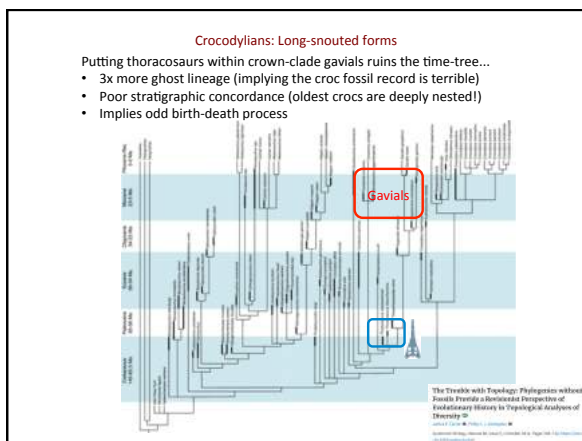

Malayan or "false" Gaviel (*Tomistoma*)

Indian Gaviel (*Gavialis*)

Thoracosaur

BEAST to the rescue ?

Data

- 117 taxa including thoracosaurus
- 278 morphological traits
- 9200 bp

Total evidence tip-dating in BEAST / BEASTM3

- Separate UCLN clocks
- Morph: Lewis, ascertainment, gamma, unpartitioned by state number

BEAST to the rescue ?

Thoracosaurus are an early, basal lineage of crocs which convergently evolved gavial-like snouts (pp 0.99)

BEAST to the rescue ?

Bayesian Inference and Phenotypic Data

- Bayesian phylogenetics (especially BEAST) has a lot to offer for morphologists and palaeontologists
- Peculiarities of morphological / palaeontological data
- Some case studies
 - Cambrian trilobites (evolutionary rates)
 - Crocodile evolution (detecting convergent evolution)
 - Lizard viviparity (ancestral state reconstruction)

Ancestral State Reconstruction

Ancestral State Reconstruction

Ancestral States: Why relaxed clocks matter!

- Biologists are tracing the evolution of traits on increasingly large trees (e.g. 10 000 birds, 6000 mammals, 4000 lizards and snakes).

Ancestral States: Why relaxed clocks matter!

- Biologists are tracing the evolution of traits on increasingly large trees (e.g. 10 000 birds, 6000 mammals, 4000 lizards and snakes).
- Traits are never going to evolve at the same rate across such large swathes of the tree of life ...

Ancestral States: Why relaxed clocks matter!

- Biologists are tracing the evolution of traits on increasingly large trees (e.g. 10 000 birds, 6000 mammals, 4000 lizards and snakes).
- Traits are never going to evolve at the same rate across such large swathes of the tree of life ...
- If you don't account for this (e.g. random local clocks), you can get **totally erroneous** ancestral state reconstructions under Bayesian or Likelihood models (or BiSSE etc).

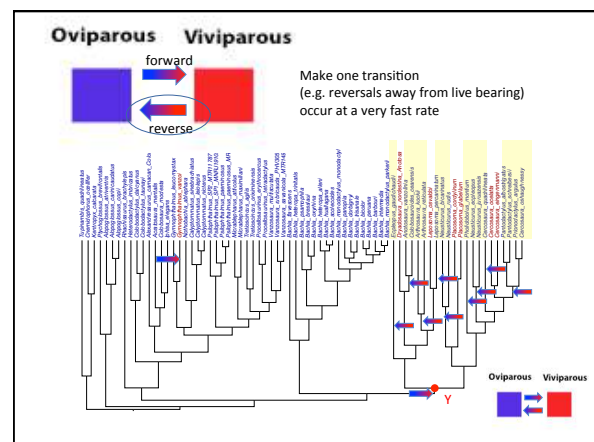

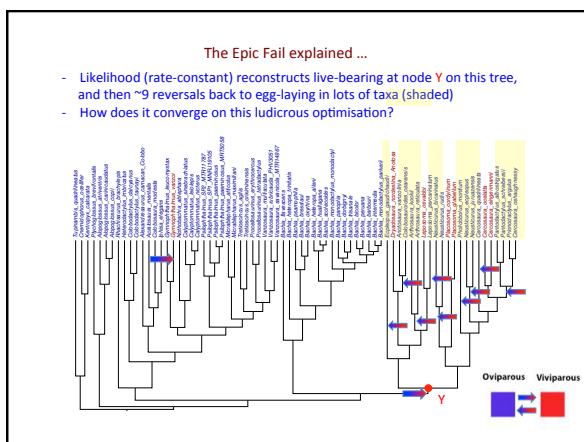

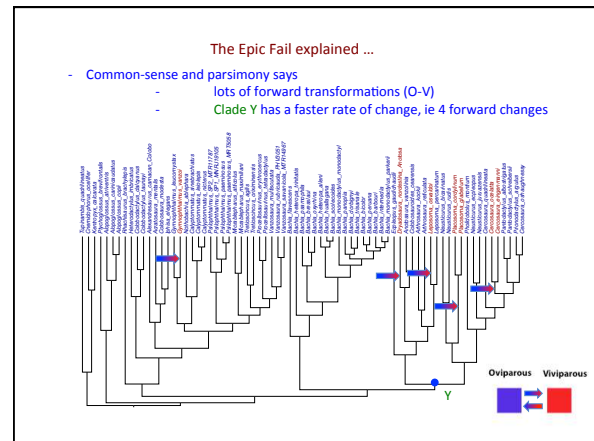

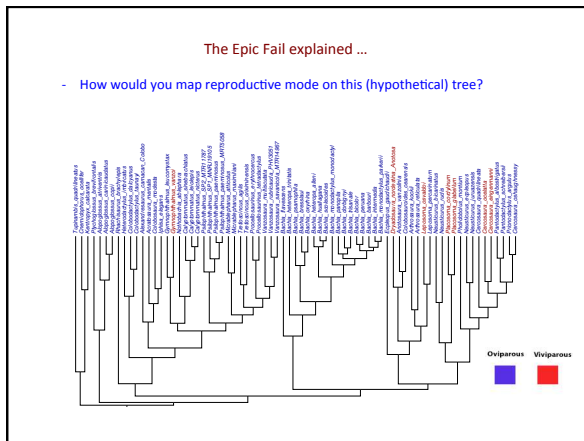

The likelihood model used by most people..

- Rate of evolution is homogenous throughout the tree (strict clock)
- But the asymmetry (forward-reverse bias) is estimated, ie a parameter that can be optimised and used to explain the observed data

Oviparous Viviparous

- Likelihood's goofy solution to explain "fast evolving" clades:
 - Give one particular transition (e.g. reversals) a very high rate, so it should occur often
 - contrive a reconstruction that has lots of these transitions in fast clades

BEAST to the rescue

Results – normality restored

- Egg-laying is ancestral for lizards and snakes
- About 100 convergent evolutions of live-bearing
- Only 3-4 reversals back to egg laying (all biologically sensible)
- Rate shifts all very sensible

BEAST to the rescue

Results – normality restored

- Egg-laying is ancestral for lizards and snakes
- About 100 convergent evolutions of live-bearing
- Only 3-4 reversals back to egg laying (all biologically sensible)
- Rate shifts all very sensible

Number of rate shifts is dependent on prior
But branch rates are not!

Bayesian Inference and Phenotypic Data
